1.1 Supplementary Figures

Supplementary Figure 1. To determine possible cytotoxic effects of the peptides used, viability of Vero cells was assessed after 48 h contact with different peptides or vehicle only and compared with the untreated (negative control) and 30% DMSO-treated cells (positive control). The dotted red line represents 80% viability cut-off. Data are mean \pm SD of 3 experiments. Only the positive control significantly ($p^{***} < 0.0005$) affected viability of Vero cells.
